## Heat Capacity

## DSC

Heat is not a state function, so we define a state function related to heat, $d S=d Q / T$

$$
\begin{aligned}
& \mathrm{dH}=\mathrm{VdP}+\mathrm{TdS} \\
& \text { At constant } \mathrm{P}(\mathrm{dH}=\mathrm{TdS}=\mathrm{dQ})_{\mathrm{P}} \\
& \text { We have } \mathrm{C}_{\mathrm{p}}=(\mathrm{dH} / \mathrm{dT})_{\mathrm{P}}=(\mathrm{dQ} / \mathrm{dT})_{P}
\end{aligned}
$$

$$
\begin{equation*}
-S \quad U(E) V \tag{array}
\end{equation*}
$$

In the DSC we measure the heat flow dQ/dt (Watts) at a constant heating rate $\mathrm{dT} / \mathrm{dt}$ at constant pressure, $(\mathrm{dQ} / \mathrm{dT})_{\mathrm{P}}=\mathrm{C}_{\mathrm{p}}$
So, the y -axis is $\mathrm{C}_{\mathrm{p}}$ times $\mathrm{dT} / \mathrm{dt}$ the latter of which is constant

Derive the expression for $\mathrm{C}_{\mathrm{p}}-\mathrm{C}_{\mathrm{V}}$

$$
\begin{aligned}
& \mathrm{C}_{\mathrm{p}}-\mathrm{C}_{\mathrm{v}}=\alpha^{2} \mathrm{VT} / \kappa_{\mathrm{T}} \\
& \alpha=(1 / \mathrm{V})(\mathrm{dV} / \mathrm{dT})_{\mathrm{p}} \\
& \kappa_{\mathrm{T}}=(1 / \mathrm{V})(\mathrm{dV} / \mathrm{dP})_{\mathrm{T}}
\end{aligned}
$$

## From Chapter 1

$\mathrm{C}_{\mathrm{V}}=(\mathrm{dU} / \mathrm{dT})_{\mathrm{V}}$
From the Thermodynamic Square
$\mathrm{dU}=\mathrm{TdS}-\mathrm{pdV}$ and, $\mathrm{C}_{\mathrm{V}}=(\mathrm{dU} / \mathrm{dT})_{\mathrm{V}}=\mathrm{T}(\mathrm{dS} / \mathrm{dT})_{\mathrm{V}}-\mathrm{p}(\mathrm{dV} / \mathrm{dT})_{\mathrm{V}}$
Second term is $0, d V$ at constant $V$ is 0
$(\mathrm{dS} / \mathrm{dT})_{\mathrm{V}}=\mathrm{C}_{\mathrm{V}} / \mathrm{T}$
Similarly
$\mathrm{C}_{\mathrm{p}}=(\mathrm{dH} / \mathrm{dT})_{\mathrm{p}}$
From the Thermodynamic Square
$\mathrm{dH}=\mathrm{TdS}+\mathrm{Vdp}$ so $\mathrm{C}_{\mathrm{p}}=(\mathrm{dH} / \mathrm{dT})_{\mathrm{p}}=\mathrm{T}(\mathrm{dS} / \mathrm{dT})_{\mathrm{p}}-\mathrm{V}(\mathrm{dp} / \mathrm{dT})_{\mathrm{p}}$
Second term is $0, \mathrm{dp}$ at constant p is 0
$(\mathrm{dS} / \mathrm{dT})_{\mathrm{p}}=\mathrm{C}_{\mathrm{p}} / \mathrm{T}$
Write a differential expression for dS as a function of T and V
$\mathrm{dS}=(\mathrm{dS} / \mathrm{dT})_{\mathrm{V}} \mathrm{dT}+(\mathrm{dS} / \mathrm{dV})_{\mathrm{T}} \mathrm{dV}$ using expression for $\mathrm{C}_{\mathrm{V}}$ above and Maxwell for $(\mathrm{dS} / \mathrm{dV})_{\mathrm{T}}$
$\mathrm{dS}=\mathrm{C}_{\mathrm{V}} / \mathrm{TdT}+(\mathrm{dp} / \mathrm{dT})_{\mathrm{V}} \mathrm{dV}$ use chain rule: $(\mathrm{dp} / \mathrm{dT})_{\mathrm{V}}=-(\mathrm{dV} / \mathrm{dT})_{\mathrm{p}}(\mathrm{dP} / \mathrm{dV})_{\mathrm{T}}=\mathrm{V} \alpha /\left(\mathrm{V} \kappa_{\mathrm{T}}\right)$
Take the derivative for $\mathrm{C}_{\mathrm{p}}: \mathrm{C}_{\mathrm{p}} / \mathrm{T}=(\mathrm{dS} / \mathrm{dT})_{\mathrm{p}}=\mathrm{C}_{\mathrm{V}} / \mathrm{T}(\mathrm{dT} / \mathrm{dT})_{\mathrm{p}}+\left(\alpha / \kappa_{\mathrm{T}}\right)(\mathrm{dV} / \mathrm{dT})_{\mathrm{p}}=\mathrm{C}_{\mathrm{V}} / \mathrm{T}+\left(\mathrm{V} \alpha^{2} / \kappa_{\mathrm{T}}\right)$ $\mathrm{C}_{\mathrm{p}}-\mathrm{C}_{\mathrm{v}}=\alpha^{2} \mathrm{VT} / \kappa_{\mathrm{T}}$

## Heat Capacity

Internal Energy of a gas

$$
U=\sum_{i=1}^{N} \frac{1}{2} m_{i} \boldsymbol{c}_{i}^{2}+\Phi\left(\boldsymbol{r}_{1}, \boldsymbol{r}_{2}, \boldsymbol{r}_{3}, \ldots, \boldsymbol{r}_{N}\right)
$$

For an ideal gas, the potential is 0

$$
\begin{aligned}
& \frac{1}{2} m<c^{2}>=\frac{3 k_{\mathrm{B}} T}{2} \quad \begin{array}{l}
\text { Monoatomic Gas: Ar } \\
3 \text { translational degrees of freedom each with } 1 / 2 \mathrm{kT} \text { energy }
\end{array} \\
& U_{\mathrm{m}}=L \frac{3}{2} k_{\mathrm{B}} T=\frac{3}{2} R T \quad C_{V, \mathrm{~m}}=\left(\frac{\partial U_{\mathrm{m}}}{\partial T}\right)_{V}=\frac{3}{2} R \\
& \text { Linear molecule, } \mathrm{CO}_{2} \text {, can rotate in two axes, } \mathrm{C}_{\mathrm{V}, \mathrm{~m}}=5 / 2 \mathrm{R} \\
& \text { Non-Linear, } \mathrm{H}_{2} \mathrm{O}, \text { can rotate in three axes, } \mathrm{C}_{\mathrm{V}, \mathrm{~m}}=6 / 2 \mathrm{R} \\
& \text { Plus, vibrational degrees of freedom }
\end{aligned}
$$

We calculate $\mathrm{C}_{\mathrm{V}}$ since all models assume constant volume We measure $\mathrm{C}_{\mathrm{p}}$ since calorimetric measurements are made at atmospheric pressure

From $\mathrm{C}_{\mathrm{V}}$ for an ideal gas, you add R to obtain $\mathrm{C}_{\mathrm{p}}$

$$
C_{p, \mathrm{~m}}-C_{V, \mathrm{~m}}=\frac{\alpha^{2} T V}{\kappa_{T}} \quad \begin{aligned}
& \text { For an ideal gas } \mathrm{PV}=\mathrm{RT} \\
& \alpha \text { is }(\mathrm{dV} / \mathrm{dT})_{\mathrm{p}} / \mathrm{V}=\mathrm{R} / \mathrm{PV}=1 / \mathrm{T} \\
& \\
& \\
& \\
& \\
& \\
& \mathrm{C}_{\mathrm{p}} \text { is }-(\mathrm{dV} / \mathrm{dP})_{\mathrm{T}} / \mathrm{V}=\mathrm{V}=(1 / \mathrm{T})^{2}(\mathrm{TV}) \mathrm{P}=\mathrm{P}=\mathrm{P}=1 / \mathrm{P} / \mathrm{T}=\mathrm{R}
\end{aligned}
$$

For other materials you need to know the thermal expansion coefficient and compressibility as a function of temperature.

## Heat Capacity, multi-atomic gasses and vibrations

$$
U_{\mathrm{m}}=L \frac{3}{2} k_{\mathrm{B}} T=\frac{3}{2} R T \quad C_{V, \mathrm{~m}}=\left(\frac{\partial U_{\mathrm{m}}}{\partial T}\right)_{V}=\frac{3}{2} R
$$

Linear molecule, $\mathrm{CO}_{2}$, can rotate in two axes, $\mathrm{C}_{\mathrm{V}, \mathrm{m}}=5 / 2 \mathrm{R}$ Non-Linear, $\mathrm{H}_{2} \mathrm{O}$, can rotate in three axes, $\mathrm{C}_{\mathrm{V}, \mathrm{m}}=6 / 2 \mathrm{R}$
Plus, vibrational degrees of freedom

Potential and Kinetic degrees of vibrational freedom add 2(R/2) for each type of vibration

Generally, $3 \mathrm{n}-6$ vibrational modes
(For linear $3 \mathrm{n}-5$ so for $\mathrm{CO}_{2} 4$ modes symmetric stretch, asymmetric stretch, two dimensions of bend)

$$
\begin{array}{ll}
\text { For an ideal gas } & \begin{array}{l}
\mathrm{PV}=\mathrm{RT} \\
\mathrm{dV} / \mathrm{dT}=\mathrm{R} / \mathrm{P} \\
\mathrm{dV} / \mathrm{dP}=-\mathrm{RT} / \mathrm{P}^{2}
\end{array} \\
C_{p, \mathrm{~m}}-C_{V, \mathrm{~m}}=\frac{\alpha^{2} T V}{\kappa_{T}}=R \quad \begin{array}{l}
\alpha=1 / \mathrm{V}(\mathrm{dV} / \mathrm{dT})=\mathrm{R} / \mathrm{PV}=1 / \mathrm{T} \\
\\
\\
\\
\\
\\
\\
\\
\\
\alpha^{2}=-1 / \mathrm{VV} / \kappa_{\mathrm{T}}=\mathrm{dV} / \mathrm{VP} / \mathrm{T}=\mathrm{RT} / \mathrm{VP}^{2}=1 / \mathrm{P}
\end{array}
\end{array}
$$

Table 8.1 Number of modes and heat capacity of gases in the classical limit.

|  | Number of modes |  |  | Classical |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  | Translational | Rotational | Vibrational |  | $C_{V, \mathrm{~m}} / R$ | $C_{p, \mathrm{~m}} / R$ |
| $\mathrm{~A}(\mathrm{~g})$ |  |  |  |  |  |  |

Figure 8.2 Molar heat capacity at constant pressure of $\mathrm{H}(\mathrm{g}), \mathrm{H}_{2}(\mathrm{~g})$ and $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$. The open symbols at 5000 K represent the limiting classical heat capacity.

Figure 3.9 Heat capacity at constant volume of one molecule of $\mathrm{H}_{2}$ in the gas phase. The vertical scale is in fundamental units; to obtain a value in conventional units, multiply by $k_{\mathrm{g}}$. The contribution from the thrce translational degrees of freedom is $\frac{3}{2}$; the contribution at high temperatures from the two rotational degrees of freedorn is 1; and the contribution
Figure 8.2 Molar h symbols at $5000 \mathrm{~K}_{1}$
from the potential and kinetic energy of the vibrational motion in the high temperature limit is 1 . The classical limits are attained when $\tau \geqslant$ refevant energy level separations.
] Monoatomic $\mathrm{H}(\mathrm{g})$ with only translational degrees of freedom is already fully excited at low temperatures. The vibrational frequencies (n) of $\mathrm{H} 2(\mathrm{~g})$ and $\mathrm{H} 2 \mathrm{O}(\mathrm{g})$ are much higher, in the range of 100 THz , and the associated energy levels are significantly excited only at temperatures above 1000 K . At room temperature only a few molecules will have enough energy to excite the vibrational modes, and the heat capacity is much lower than the classical value. The rotational frequencies are of $00^{\text {the }}$ order 100 times smaller, so they are fully excited above $\sim 10 \mathrm{~K}$.

## id $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$. The open

## Dulong and Petit Law (Observation, heat capacity of solids)

$$
\mathrm{C}_{\mathrm{V}} / \mathrm{n}=3 \mathrm{R} \quad(25 \mathrm{~J} /(\mathrm{mol} \mathrm{~K})
$$

This agreement is because in the classical statistical theory of Ludwig Boltzmann, the heat capacity of solids approaches a maximum of $3 R$ per mole of atoms because full vibrational-mode degrees of freedom amount to 3 degrees of freedom per atom, each corresponding to a kinetic energy term and a potential energy term. By the equipartition theorem, the average of each term is $1 / 2 k_{\mathrm{B}} T$ per atom, or $\frac{1}{2} R T$ per mole. Multiplied by 3 degrees of freedom ( $x, y, z$ ) and the two terms per degree of freedom (kinetic and potential), this amounts to $3 R$ per mole heat capacity.

## Dulong and Petit Law (Observation for Solids)

## Dulong and Petit Law (Observation for solids)

Fails for strongly bound light atoms

## Atoms in a crystal (Dulong and Petit Law)

## Works at high temperature

Three Harmonic oscillators, $\mathrm{x}, \mathrm{y}, \mathrm{z}$
Spring (Potential Energy)
$\mathrm{dU} / \mathrm{dx}=\mathrm{F}=-\mathrm{kx}$ where x is 0 at the rest position $\mathrm{U}=-1 / 2 \mathrm{kx}{ }^{2}$
Kinetic Energy
$\mathrm{U}=1 / 2 \mathrm{mc}^{2}$
c is the velocity of the atom so $\mathrm{dx} / \mathrm{dt}$

Force Balance

$$
-\mathrm{Kx}=\mathrm{m} \mathrm{~d}^{2} \mathrm{x} / \mathrm{dt}^{2}
$$

Plug in a sine wave solution,

$$
x=A \sin (\omega t)
$$

Yields $\omega=\sqrt{ }(\mathrm{K} / \mathrm{m})$
So, there is a fixed frequency for a fixed spring constant and mass, since $E=h \omega / 2 \pi$, there is a fixed or quantized energy

$$
\begin{aligned}
& U=\frac{1}{2} m c^{2}+\frac{1}{2} K x^{2}=\frac{1}{2} m A^{2} \omega^{2} \cos ^{2} \omega t+\frac{1}{2} K A^{2} \sin ^{2} \omega t \\
& x=A \sin \omega t \quad \omega=2 \pi v=\sqrt{\frac{K}{m}}
\end{aligned}
$$

Three degree of freedom oscillators per atom so $U_{m}=3 R T$

$$
\mathrm{dU}=-\mathrm{pdV}+\mathrm{TdS}
$$

$$
C_{V, \mathrm{~m}}=3 R=24.94 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}
$$

## Atoms in a crystal (Dulong and Petit Law) Works at high temperature

Force Balance

$$
-K x=\mathrm{m} \mathrm{~d}^{2} \mathrm{x} / \mathrm{dt}^{2}
$$

Plug in a sine wave solution,

$$
x=A \sin (\omega t)
$$

Yields $\omega=\sqrt{ }(\mathrm{K} / \mathrm{m})$
So, there is a fixed frequency for a fixed spring constant and mass, since $E=h \omega / 2 \pi$, there is a fixed or quantized energy

For something like a guitar string, we have quantized energy and frequency, it has one tone, but also overtones so, $\mathbf{E}=\mathbf{n} \mathbf{E}_{\mathbf{1}}$ where n is the mode of vibration or quantized state, and $\mathbf{n}$ has integer values starting with $\mathbf{1}$. $\mathrm{E}_{1}$ is the energy of the primary mode, $\mathrm{E}_{1}=(1 / 2) \rho v^{2} \mathrm{~A}^{2}$ density, (frequency) ${ }^{2}$ and (magnitude) ${ }^{2}$ of the vibration.

For quantum mechanics (very small particles like atoms) there is a problem with $\mathrm{E}=\mathrm{nh} \nu$ or $\mathrm{nh} \omega / 2 \pi$

1) At absolute 0 there is a "zero-point energy" that keeps everything from collapsing for instance, we don't observe
collapse as we approach absolute 0 . Schrodinger equation finds this zero-point energy is $1 / 2 \mathrm{~h} v$
2) If energy were 0 at absolute 0 then we would know both the position of an and its momentum $=0$

This would disagree with the Heisenberg uncertainty principle. So, you need a "zero-point energy"
3) A "zero-point energy" can be measured experimentally
$\mathbf{E}=\mathbf{h} \boldsymbol{\nu}(\mathbf{1} / \mathbf{2}+\mathbf{n})$ and n has integer values starting at 0 for the ground state energy.

Consider the crystal is made up of free atoms confined into boxes as harmonic oscillators in 3D, x, y, z. All the atoms have the same Einstein frequency, $\boldsymbol{v}_{\mathbf{E}}$. There are then, $\mathbf{3 N}$ "independent" harmonic oscillators, where N is the number of moles of atoms in the crystal. First consider on harmonic oscillator using $k$ then multiply by 3 N to get 3 R .

The energy of one harmonic oscillator for quantum state (mode) " $n$ " is $\boldsymbol{\varepsilon}_{\mathbf{n}}=\mathbf{h} \boldsymbol{v}_{\mathbf{E}}(\mathbf{1 / 2}+\mathbf{n})$ where n is $0,1,2,3, \ldots, \infty$ The harmonic oscillators are at equilibrium at temperature T so the partition function (Zustandssumme, sum of states), $Z=\sum_{n=0}^{\infty} \exp \left(-\beta \varepsilon_{n}\right)=\sum_{n=0}^{\infty} \exp \left(-\beta h v_{E}\left(n+\frac{1}{2}\right)\right)=e^{-x / 2} \sum_{n=0}^{\infty} e^{-x n} \quad$ where $x=\beta h v_{E}$ and $\beta=1 / k T$ Sum of geometric progress series $\sum_{n=0}^{\infty} x^{n}=\frac{1}{1-x}$
$Z=\frac{e^{-x / 2}}{1-e^{-x}} \quad$ Note that this explicitly includes the ground state energy, if you start with just an energy you get $\mathrm{Z}=1 /\left(1-\mathrm{e}^{-x}\right)$
Equipartition theorem: Energy is partitioned according to the probability of states
The average energy $=\langle\mathrm{U}\rangle=\sum_{n=0}^{\infty} \frac{\varepsilon_{n} \exp (-n x)}{Z}=-\frac{1}{Z} \frac{d Z}{d \beta}=-\frac{d \ln Z}{d \beta}=h v_{E} \frac{e^{-\beta h v_{e}}}{1-e^{-\beta h v_{e}}}=h v_{E} \frac{e^{-h v_{e} / k T}}{1-e^{-h v_{e} / k T}}=\frac{h v_{E}}{e^{h v_{e} / k T}-1}$
$C_{V}=\left(\frac{d U}{d T}\right)_{V}=k\left(\frac{h v_{e}}{k T}\right)^{2} \frac{e^{\frac{h v_{e}}{k T}}}{\left(e^{\frac{h v_{e}}{k T}}-1\right)^{2}}=k\left(\frac{\theta_{E}}{T}\right)^{2} \frac{e^{\frac{\theta_{E}}{T}}}{\left(e^{\frac{\theta_{E}}{T}}-1\right)^{2}} \quad$ For 3N $\quad C_{V}$ per mole $=3 R\left(\frac{\theta_{E}}{T}\right)^{2} \frac{e^{\frac{\theta_{E}}{T}}}{\left(e^{\frac{\theta_{E}}{T}}-1\right)^{2}} \quad \theta_{E}=\frac{h v_{E}}{k}$

## Phonons From Dove

## Einstein Model

Works at low and high temperature
Lower at low temperature

Figure 8.3 Experimental heat capacity of Cu at constant pressure compared with $C_{V, \mathrm{~m}}$ calculated by the Einstein model using $\Theta_{\mathrm{E}}=244 \mathrm{~K}$. The vibrational frequency used in the Einstein model is shown in the insert.

## Einstein Model

## Works at low and high temperature

## Lower at low temperature

$$
C_{V, \mathrm{~m}}=3 R=24.94 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}
$$

Figure 8.3 Experimental heat capacity of Cu at constant pressure compared with $C_{V, \mathrm{~m}} \mathrm{c}$ : culated by the Einstein model using $\Theta_{\mathrm{E}}=244 \mathrm{~K}$. The vibrational frequency used in the Ei ctain modal ic chnoun in the incart

## Debye Model Works

Figure 8.12 Experimental heat capacity of Cu at constant pressure compared with the Debye and Einstein $C_{V, \mathrm{~m}}$ calculated by using $\Theta_{\mathrm{E}}=244 \mathrm{~K}$ and $\Theta_{\mathrm{D}}=314 \mathrm{~K}$. The vibrational density of states according to the two models is shown in the insert.

## Average Energy and the Partition Function

Consider a set of N independent (No Enthalpy) molecules at different energy states, $\mathrm{N}_{\mathrm{i}}$ molecules at $\mathrm{E}_{\mathrm{i}}$ The average energy is $E=\sum_{i} N_{i} E_{i}$
The Boltzmann Probability gives $N_{i}=\sum_{i} \frac{N e^{-E_{i} / k T}}{Z}$ and $Z=\sum_{i} e^{-E_{i} / k T}$ is the partition function Then $E=\frac{N}{Z} \sum_{i} E_{i} e^{-E_{i} / k T}$
Consider $\frac{d}{d T} e^{-E_{i} / k T}=+\frac{E_{i}}{k T^{2}} e^{-E_{i} / k T}$ so $E_{i} e^{-E_{i} / k T}=k T^{2} \frac{d}{d T} e^{-E_{i} / k T}$

$$
E=\frac{N k T^{2}}{Z} \sum_{i} \frac{d}{d T} e^{-E_{i} / k T}
$$

$$
E d T=\frac{N k T^{2}}{Z} d Z
$$

$$
E=-N k T \ln Z
$$

For ground state $E=0, Z$ at $T=0$ is 1 ; for $T=\infty, Z$ is the number of states (degeneracy)
For molecular vibrations $E=\mathrm{h} \omega$

## Electronic Contribution to Heat Capacity (Briefly)

Hence, only a very small fraction of electrons, those lying within $\sim k \Delta T$ of the Fermi level, are able to absorb the energy and contribute to the heat capacity.

The heat capacity per electron turns out to be

$$
C_{V}=\frac{\pi^{2}}{2} k \frac{T}{T_{F}}
$$

Einstein Temp. Copper 236K Aluminum 294K Lead 72.8 K Iron 355 K

At room temperature this is a very small contribution to the overall heat capacity (on the order of a few percent). However, at very low temperatures the electronic heat capacity dominates, since it is linear in temperature while the lattice heat capacity is proportional to $T^{3}$.
http://vallance.chem.ox.ac.uk/pdfs/EinsteinDebye.pdf

Table 8.2. Debye temperature ( $\Theta_{\mathrm{D}}$ in K ) and electronic heat capacity coefficient (see Section 8.4) $\left(\gamma \mathrm{in} \mathrm{mJ} \mathrm{K}{ }^{-1} \mathrm{~mol}^{-1}\right)$ of the elements.

$$
\text { For } \mathrm{T}<10 \mathrm{~K}
$$

$$
C_{V}=\beta T^{3}+\gamma T
$$

Figure 8.21 Heat capacity of Cu plotted as $C_{p, \mathrm{~m}} \cdot T^{-1}$ versus $T^{2}$

## 1907 Einstein Solid Model for Dulong Petit Law at high kT

Energy is quantized, quantum number is " $n$ " goes from 1 to positive integer values for the principal quantum number
Smallest quantum of energy is $\varepsilon=\mathrm{h} v$
Energy for quantum number " $n$ " is
$\mathrm{E}_{\mathrm{n}}=\mathrm{h} v(\mathrm{n}+1 / 2)=\varepsilon(\mathrm{n}+1 / 2)$
Total number of quantum states N
Total energy $\mathrm{N} \varepsilon(\mathrm{n}+1 / 2)$
Ground state energy $\mu$
Geometric Series $\quad \sum_{k=0}^{\infty} a r^{k}=\frac{a}{1-r}$

$$
\begin{aligned}
\mathcal{Z} & =\sum_{N=0}^{\infty} \exp \left(N(\mu-\varepsilon) / k_{\mathrm{B}} T\right)=\sum_{N=0}^{\infty}\left[\exp \left((\mu-\varepsilon) / k_{\mathrm{B}} T\right)\right]^{N} \\
& =\frac{1}{1-\exp \left((\mu-\varepsilon) / k_{\mathrm{B}} T\right)} .
\end{aligned}
$$

## 1907 Einstein Solid Model for Dulong Petit Law at high kT

$$
\begin{aligned}
& \mathcal{Z}=\sum_{N=0}^{\infty} \exp \left(N(\mu-\varepsilon) / k_{\mathrm{B}} T\right)=\sum_{N=0}^{\infty}\left[\exp \left((\mu-\varepsilon) / k_{\mathrm{B}} T\right)\right]^{N} \\
&=\frac{1}{1-\exp \left((\mu-\varepsilon) / k_{\mathrm{B}} T\right)} . \\
& \text { Energy }=-\mathrm{kT} \log (\mathrm{Z}) ; \log (1 / \mathrm{Z})=-\log (\mathrm{Z})
\end{aligned}
$$

A system of vibrations in a crystalline solid lattice can be modelled as an Einstein solid, i.e. by considering $N$ quantum harmonic oscillator potentials along each degree of freedom. Then, the free energy of the system can be written as ${ }^{[1]}$

$$
F=N \varepsilon_{0}+N k_{\mathrm{B}} T \sum_{\alpha} \log \left(1-e^{-\hbar \omega_{\alpha} / k_{\mathrm{B}} T}\right) \quad \exp (\mathrm{x})=1+\mathrm{x}+\mathrm{x} 2 / 2!+\mathrm{x} 3 / 3!+\ldots \text { At high } \mathrm{kT}=>\log (\mathrm{h} v / \mathrm{kT})
$$

$$
F=N \varepsilon_{0}+N k_{\mathrm{B}} T \sum_{\alpha} \log \left(\frac{\hbar \omega_{\alpha}}{k_{\mathrm{B}} T}\right)
$$

$F$ is $\mathrm{A} ; \mathrm{E}$ is U
Define geometric mean frequency by

$$
\log \bar{\omega}=\frac{1}{g} \sum_{\alpha} \log \omega_{\alpha}
$$

where $g$ measures the total number of spatial degrees of freedom of the system.

## Einstein Derivation of Dulong Petit

S $\quad \mathrm{E}) \quad \mathrm{V}$
H

$$
\begin{aligned}
& \mathrm{U}=\mathrm{A}+\mathrm{TS} \\
& \mathrm{dA}=-\mathrm{SdT}-\mathrm{pdV} \quad-\mathrm{p} \quad \text { G } \quad \text { T } \\
& (\mathrm{dA} / \mathrm{dT})_{\mathrm{V}}=-\mathrm{S} \\
& \mathrm{U}=\mathrm{A}-\mathrm{T}(\mathrm{dA} / \mathrm{dT})_{\mathrm{V}} \\
& \mathrm{~A}=\mathrm{NE}_{0}+\mathrm{NkT} \sum_{i} \log \left(\frac{h \omega_{i}}{k T}\right) \\
& (\mathrm{dA} / \mathrm{dT})_{\mathrm{V}}=\mathrm{Nk} \sum_{i}\left(\log \left(\frac{h \omega_{i}}{k T}\right)-N k T\left(\frac{-1}{T}\right)\right) \quad \mathrm{d} \ln \mathrm{x}=\mathrm{dx} / \mathrm{x} \quad \log \bar{\omega}=\frac{1}{g} \sum_{\alpha} \log \omega_{\alpha}, \\
& \mathrm{U}=\mathrm{NE}_{0}+\mathrm{NkT} \sum_{i} \log \left(\frac{h \omega_{i}}{k T}\right) \\
& -\mathrm{NkT} \sum_{i} \log \left(\frac{h \omega_{i}}{k T}\right)-\sum_{i} N k T \quad \mathrm{~g} \text { is number of DOF or } 3 \\
& =\mathrm{NE}_{0}+\mathrm{gNkT} \\
& C_{V}=(\mathrm{dU} / \mathrm{dT})_{\mathrm{V}}=\mathrm{gNk}=3 \mathrm{Nk}
\end{aligned}
$$

## 1907 Einstein Solid Model for Dulong Petit Law at high kT

$$
F=N \varepsilon_{0}+N k_{\mathrm{B}} T \sum_{\alpha} \log \left(\frac{\hbar \omega_{\alpha}}{k_{\mathrm{B}} T}\right)
$$

F is $A$; $E$ is $U$

$$
F=N \varepsilon_{0}-g N k_{\mathrm{B}} T \log k_{\mathrm{B}} T+g N k_{\mathrm{B}} T \log \hbar \bar{\omega} .
$$

Using energy

$$
E=F-T\left(\frac{\partial F}{\partial T}\right)_{V}
$$

we have

$$
E=N \varepsilon_{0}+g N k_{\mathrm{B}} T
$$

This gives heat capacity at constant volume

$$
C_{V}=\left(\frac{\partial E}{\partial T}\right)_{V}=g N k_{\mathrm{B}}, \quad \quad \text { Molar } \mathrm{C}_{\mathrm{v}} / \mathrm{N}=\mathrm{gk} \text { or } \mathrm{C}_{\mathrm{v}}=3 \mathrm{R} \text { in } 3 \mathrm{~d}
$$

## Crystal of lattice spacing a; Sound waves of wavelength $\lambda$ or $k$ vector $2 \pi / \lambda$

## Phonons

Two size scales, a and $\lambda$
If $\lambda \geq$ a you are within a Brillouin Zone
Wavevector $\mathrm{k}=2 \pi / \lambda$

k -vectors exceeding the first Brillouin zone (red) do not carry any more information than their counterparts (black) in the first Brillouin zone.

Black are atoms subject to a high frequency sound (red)

Phonons Two size scales, a and $\lambda$
If $\lambda \geq$ a you are within a Brillouin Zone
Wavevector $\mathrm{k}=2 \pi / \lambda$
k -vector is like the inverse-space vectors for the lattice (or the Miller indices)
It is seen to repeat in inverse space making an inverse lattice

A phonon with wavenumber $k$ is thus equivalent to an infinite family of phonons with wavenumbers $k \pm 2 \pi / a, k \pm 4 \pi / a$, and so forth.

Brillouin zones, (a) in a square lattice, and (b) in a hexagonal lattice

those whose bands become zero at the center of the Brillouin zone are called acoustic phonons, since they correspond to classical sound in the limit of long wavelengths. The others are optical phonons, since they can be excited by electromagnetic radiation.

## Phonons

Two size scales, a and $\lambda$
If $\lambda \geq$ a you are within a Brillouin Zone
Wavevector $\mathrm{k}=2 \pi / \lambda$
The partition function $(Z)$ can be defined in terms of energy $(\mathrm{E}), E=-N k T \ln Z$,
or in terms of the wavevector $\mathrm{k}=2 \pi / \lambda=2 \pi \mathrm{E} / \mathrm{hc}=-2 \pi N k T \ln Z / \mathrm{hc}$
E and k are related by the dispersion relationship (dispersion of energy in k )
which differs for different systems
(longitudinal, transverse, acoustic, optical phonons)
The density of states is defined by $\quad D(E)=\frac{1}{V} \cdot \frac{\mathrm{~d} Z_{m}(E)}{\mathrm{d} E} \quad \mathcal{Z}=\sum_{N=0}^{\infty} \exp \left(N(\mu-\varepsilon) / k_{\mathrm{B}} T\right)$
For a Longitudinal Phonon in a string of atoms the dispersion relation is:
Transverse is like an ocean wave or a guitar string, longitudinal is a compressive wave like sound

$$
E=2 \hbar \omega_{0}\left|\sin \left(\frac{k a}{2}\right)\right| \quad \begin{aligned}
& \sin x=x-x^{3} / 3!+x^{5} / 5!-\ldots \\
& \text { For small } x ; \sin x=x
\end{aligned}
$$

where $\omega_{0}=\sqrt{k_{\mathrm{F}} / m}$ is the oscillator frequency, $m$ the mass of the atoms, $k_{\mathrm{F}}$ the inter-atomic force constant and $a$ inter-atomic spacing.

This relates modulus to frequency

## Phonons

Dispersion Relationship is how the energy or frequency of vibrations related to the size scale or wavelengths or what happens to vibrational energy in the crystal, i.e., modulus.

$$
E=2 \hbar \omega_{0}\left|\sin \left(\frac{k a}{2}\right)\right|
$$

Density of States is how the total energy is distributed to different frequencies of vibration. This is related to what happens at different wavenumbers to different wavelength phonons.

$$
D(E)=\frac{1}{V} \cdot \frac{\mathrm{~d} Z_{m}(E)}{\mathrm{d} E} \quad \mathcal{Z}=\sum_{N=0}^{\infty} \exp \left(N(\mu-\varepsilon) / k_{\mathrm{B}} T\right)
$$

N is an integer related to the vibrational state k

## Frequency of a Harmonic Oscillator

Do a Force Balance
$\mathrm{F}=\mathrm{mx}$ " $=\mathrm{Kx}$ where K is the spring constant, m is the mass
Then $m x "-K x=0$ is a second order differential equation or $\mathrm{x} "-(\mathrm{K} / \mathrm{m}) \mathrm{x}=0$
If you know that the derivative of exponential is the exponential
Then you can guess one answer (this helps)
$x=\exp ( \pm \sqrt{ }(\mathrm{K} / \mathrm{m}) \mathrm{t}) ; \mathrm{x}^{\prime}= \pm \sqrt{ }(\mathrm{K} / \mathrm{m}) \exp ( \pm \sqrt{ }(\mathrm{K} / \mathrm{m}) \mathrm{t}) ; \mathrm{x}^{\prime \prime}=\mathrm{K} / \mathrm{m} \exp ( \pm \sqrt{ }(\mathrm{K} / \mathrm{m}) \mathrm{t})$ $\sqrt{ }(\mathrm{K} / \mathrm{m})$ and t have to have inverse units so $\sqrt{ }(\mathrm{K} / \mathrm{m})=\omega$
This is the native frequency of the oscillator

## Phonons

$$
\begin{aligned}
\mathcal{Z} & =\sum_{N=0}^{\infty} \exp \left(N(\mu-\varepsilon) / k_{\mathrm{B}} T\right)=\sum_{N=0}^{\infty}\left[\exp \left((\mu-\varepsilon) / k_{\mathrm{B}} T\right)\right]^{N} \\
& =\frac{1}{1-\exp \left((\mu-\varepsilon) / k_{\mathrm{B}} T\right)}
\end{aligned}
$$

$\mu$ is the ground state energy and $\varepsilon$ is the energy of a state

$$
\begin{gathered}
\frac{1}{1-x}=\sum_{n=0}^{\infty} x^{n} \\
\text { which is valid for }|x|<1
\end{gathered}
$$

Bose-Einstein statistics gives the probability of finding a phonon in a given state:

Fig. 9.1 The Bose-Einstein distribution
$n(\omega, T)$ as a function of $k_{\mathrm{B}} T / \hbar \omega$.

## Phonons

Atoms or ions of mass $m_{1}, m_{2}$
Separated by a distance $a$
With spring constant $K$
2 modes of vibration result for a crystal with two atoms in a primitive cell

+ is optical (atoms move against each other, picture $\mathrm{Na}^{+} \mathrm{Cl}^{-}$subject to an oscillating electric field, i.e. IR light) finite value at $k=0$ reflects the polarization of the material i.e. the dielectric constant
- is acoustic (atoms move with each other) move at speed of sound. 0 energy at $k=0$ or infinite $\lambda$ means motion of the whole object

For three or more atoms in a primitive cell there are Three acoustic modes: One longitudinal (sound) and Two transverse (ocean)

Number of optical models is $3 \mathrm{~N}-3$

Dispersion relation (relating E to $\mathbf{k}$ ) for phonons
(much math to get this expression)

$$
\omega_{ \pm}^{2}=K\left(\frac{1}{m_{1}}+\frac{1}{m_{2}}\right) \pm K \sqrt{\left(\frac{1}{m_{1}}+\frac{1}{m_{2}}\right)^{2}-\frac{4 \sin ^{2} \frac{k a}{2}}{m_{1} m_{2}}}
$$

Fluids can't support shear stress so, they only have longitudinal (sound) acoustic modes

## Phonons From Dove

Phonons have energy h $\omega / 2 \pi$
The energy at 0 K is not 0 it is $1 / 2 \mathrm{~h} \omega / 2 \pi$
This is a consequence of energy quantization (lattice calculations are done at 0 K ) (Uncertainty principle)
$E=\hbar \omega\left[\frac{1}{2}+n(\omega, T)\right] \quad \begin{aligned} & \mathrm{n} \text { is the number of phonons at wavelength } \\ & \omega \text { and temperature T }\end{aligned}$

## Debye Model (Wikipedia)

For a cube of size $L$ vibrations are limited to certain modes like a string of length $L$

Modes of vibration, $n$

(Transverse Wave)

$$
\lambda_{n}=\frac{2 L}{n}
$$

$$
\begin{gathered}
E_{n}=h \nu_{n}=\frac{h c_{\mathrm{s}}}{\lambda_{n}}=\frac{h c_{s} n}{2 L} \quad \mathrm{c}_{\mathrm{s}} \text { is the speed of sound in the solid } \\
E_{n}^{2}=p_{n}^{2} c_{\mathrm{s}}^{2}=\left(\frac{h c_{\mathrm{s}}}{2 L}\right)^{2}\left(n_{x}^{2}+n_{y}^{2}+n_{z}^{2}\right) \quad \begin{array}{l}
\text { For 3d } \\
\mathrm{p}_{\mathrm{n}} \text { is the momentum of a phonon } \\
E=\sum_{n} E_{n} \bar{N}\left(E_{n}\right) \quad U=\sum_{n_{z}} \sum_{n_{y}} \sum_{n_{z}} E_{n} \bar{N}\left(E_{n}\right)
\end{array}
\end{gathered}
$$

$$
\lambda_{\min }=\frac{2 L}{\sqrt[3]{N}}, \quad \text { For } \mathrm{N} \text { atoms in the box }
$$

making the maximum mode number $n$ (infinite for photons)

$$
n_{\max }=\sqrt[3]{N}
$$

This is the highest energy vibration At high temperature all of the vibrations are excited

## Debye Model (This is borrowed by Rouse for polymer dynamics)

Figure 8.4 One-dimensional chain of atoms with interatomic distance $a$ and force constant $K$.

## Collective modes of vibration

If atom $n$ vibrates and atoms $n+1$ and $n-1$ vibrate, the potential energy of $n$ isn't independent of the motion of the neighboring atoms.
$u$ is POSITION $(x)$ and $F$ is FORCE here Before we had $\mathrm{F}=-\mathrm{Ku}$ for uncoupled pairs
Force $\quad F=-K\left(u_{n}-u_{n+1}+u_{n}-u_{n-1}\right)$
For coupled units

Force Balance

$$
m \frac{\partial^{2} u_{n}}{\partial t^{2}}=-\frac{\partial U}{\partial u_{n}}=F=-K\left(2 u_{n}-u_{n+1}-u_{n-1}\right) \quad \begin{aligned}
& F \text { is } m a \text { also } K x \text { also } \\
& \mathrm{d} U=F \mathrm{~d} x
\end{aligned}
$$

## Propose a solution:

$$
\begin{aligned}
& u_{n}=u_{0} \cos (\omega t-q n a) \text { wave vector } q=2 \pi / \lambda \\
& \text { Phase } \\
& \text { angle } \delta \begin{array}{c}
\text { Atomic spacing is "a" } \\
\text { " } \mathbf{n} " \text { is the atom index }
\end{array}
\end{aligned}
$$

Use in the equation of motion and solve for frequency

Force

$$
\begin{gathered}
m \frac{\partial^{2} u_{n}}{\partial t^{2}}=-\frac{\partial U}{\partial u_{n}}=F=-K\left(2 u_{n}-u_{n+1}-u_{n-1}\right) \\
\omega(q)=\sqrt{\frac{4 K}{m}}\left|\sin \left(\frac{q a}{2}\right)\right| \begin{array}{c}
\text { Angular frequency of vibrations as a function of wavevector, } \mathbf{q} \\
\text { This is a dispersion relation relating energy to } q \text { or wavelength }
\end{array}
\end{gathered}
$$

## Debye Dispersion Relation

$$
\omega(q)=\sqrt{\frac{4 K}{m}}\left|\sin \left(\frac{q a}{2}\right)\right|
$$

Angular frequency of vibrations as a function of wavevector, $q$ This is a dispersion relation relating energy to $q$ or wavelength

FIGURE 15.4 Dispersion curve w versus $q$ for the Einstein solid. All $3 N$ oscillators have the same Einstein frequency for wave vectors
in the accessible range 0 to $q_{m}$.
https://ebrary.net/196904/mathematics/einstein_model_specific_heat_solids

## Phonons

Two size scales, a and $\lambda$
If $\lambda \geq$ a you are within a Brillouin Zone
Wavevector $\mathrm{k}=2 \pi / \lambda$
The partition function $(Z)$ can be defined in terms of $E$ or in terms of the wavevector $k=2 \pi / \lambda=2 \pi \mathrm{E} / \mathrm{hc}$ E and k are related by the dispersion relationship which differs for different systems (longitudinal, transverse, acoustic, optical phonons)

The density of states is defined by $\quad D(E)=\frac{1}{V} \cdot \frac{\mathrm{~d} Z_{m}(E)}{\mathrm{d} E} \quad \mathcal{Z}=\sum_{N=0}^{\infty} \exp \left(N(\mu-\varepsilon) / k_{\mathrm{B}} T\right)$
For a longitudinal Phonon in a string of atoms the dispersion relation is:
Transverse is like an ocean wave or a guitar string, longitudinal is a compressive wave like sound

$$
E=2 \hbar \omega_{0}\left|\sin \left(\frac{k a}{2}\right)\right|
$$

where $\omega_{0}=\sqrt{k_{\mathrm{F}} / m}$ is the oscillator frequency, $m$ the mass of the atoms, $k_{\mathrm{F}}$ the inter-atomic force constant and $a$ inter-atomic spacing.

## Debye Dispersion Relation

$$
\omega(q)=\sqrt{\frac{4 K}{m}}\left|\sin \left(\frac{q a}{2}\right)\right|
$$

Angular frequency of vibrations as a function of wavevector, $q$ This is a dispersion relation relating energy to $q$ or wavelength

Einstein Dispersion Relation

## Debye Dispersion Relation

\begin{aligned}
& \omega_{\mathrm{a}}^{2}=K\left[\left(\frac{m_{1}+m_{2}}{m_{1} m_{2}}\right)-\frac{\sqrt{\left(m_{1}-m_{2}\right)^{2}+4 m_{1} m_{2} \cos ^{2} q a}}{m_{1} m_{2}}\right] \quad \text { Minus Acoustic } \\
& \omega_{\mathrm{o}}^{2}=K\left[\left(\frac{m_{1}+m_{2}}{m_{1} m_{2}}\right)+\frac{\sqrt{\left(m_{1}-m_{2}\right)^{2}+4 m_{1} m_{2} \cos ^{2} q a}}{m_{1} m_{2}}\right] \quad \text { Plus Optical }
\end{aligned}
$$

### 2.1.3 Normal Modes of a One-Dimensional Chain with a Basis

We consider a one-dimensional Bravais lattice of lattice constant $a$ with two ions or atoms of masses $M_{1}$ and $M_{2}$ per unit cell. This is shown in Figure 2.6. The basic assumption is that each ion interacts only with the nearest neighbors, which are at a distance $a / 2$ from each other, and $M_{1}>M_{2}$. Thus, the lattice constant of the linear chain is $a$.

If $K$ is the force constant, from Eq. (2.21) we obtain

$$
\begin{equation*}
V^{h a r m}=\frac{K}{2} \sum_{s}\left[u_{1}(s a)-u_{2}(s a)\right]^{2}+\frac{K}{2} \sum_{s}\left[u_{2}(s a)-u_{1}[s+1] a\right]^{2}, \tag{2.32}
\end{equation*}
$$

where $u_{1}(s a)$ is the displacement of the ion that oscillates about the site sa and $u_{2}(s a)$ is the displacement of the ion that oscillates around $s a+d$. The equations of motion are

$$
\begin{align*}
& M_{1} \ddot{u}_{1}(s a)=-\frac{\partial V^{h a r m}}{\partial u_{1}(s a)}=-K\left[2 u_{1}(s a)-u_{2}(s a)-u_{2}([s-1] a)\right], \\
& M_{2} \ddot{u}_{2}(s a)=-\frac{\partial V^{h a r m}}{\partial u_{2}(s a)}=-K\left[2 u_{2}(s a)-u_{1}(s a)-u_{1}([s+1] a)\right] . \tag{2.33}
\end{align*}
$$

The solutions of Eq. (2.33) are of the type

$$
u_{1}(s a, t)=\epsilon_{1} e^{j(q s a-a N)}
$$

hysics of Condensed Matter By Prasanta Misra

$$
\begin{equation*}
u_{2}(s a, t)=\epsilon_{2} e^{i(q s a-a t)} \tag{2.34}
\end{equation*}
$$

Substituting Eq. (2.34) in Eq. (2.33), we obtain
and

$$
\begin{equation*}
-\omega^{2} M_{1} Є_{1} e^{i(q s a-\omega t)}=K\left(Є_{2}-2 Є_{1}+Є_{2} e^{-i q a}\right) e^{i(q s a-\omega t)} \tag{2.35}
\end{equation*}
$$

We cancel the $e^{i(q s a-\omega s)}$ term from both sides and solve the determinantal equation

$$
\left|\begin{array}{cc}
2 K-M_{1} \omega^{2} & -K\left(1+e^{-i q a}\right)  \tag{2.36}\\
-K\left(1+e^{i q a}\right) & 2 K-M_{2} \omega^{2}
\end{array}\right|=0
$$

There are two roots of the solution of Eq. (2.36), which yields (Problem 2.4)

$$
\begin{equation*}
\omega_{ \pm}^{2}=K\left(\frac{1}{M_{1}}+\frac{1}{M_{2}}\right) \pm K \sqrt{\left[\left(\frac{1}{M_{1}}+\frac{1}{M_{2}}\right)^{2}-\frac{4 \sin ^{2}(q a / 2)}{M_{1} M_{2}}\right]} . \tag{2.37}
\end{equation*}
$$

The two solutions of Eq. (2.37) are the two branches of the phonon dispersion relation. For small $q$, the two roots of Eq. (2.37) are

$$
\begin{equation*}
\omega_{-}=\sqrt{\frac{K}{2\left(M_{1}+M_{2}\right)}} q a \tag{2.38}
\end{equation*}
$$

and

$$
\begin{equation*}
\omega_{+}=\sqrt{\frac{2 K\left(M_{1}+M_{2}\right)}{M_{1} M_{2}}} . \tag{2.39}
\end{equation*}
$$

We also note from Eq. (2.37) that if $q a= \pm \pi$ (the Brillouin zone boundary), the expressions for $\omega_{ \pm}$reduce to

$$
\omega_{ \pm}^{2}=\left(K\left[\frac{1}{M_{1}}+\frac{1}{M_{2}}\right] \pm K\left[\frac{1}{M_{2}}-\frac{1}{M_{1}}\right]\right) .
$$

Thus, we obtain

$$
\begin{equation*}
\omega_{+}=\sqrt{\frac{2 K}{M_{2}}} \tag{2.41}
\end{equation*}
$$

and

$$
\begin{equation*}
\omega_{-}=\sqrt{\frac{2 K}{M_{1}}} \tag{2.42}
\end{equation*}
$$

At the Brillouin zone boundary, $q= \pm \frac{\pi}{a}$ We also note that because $M_{1}>M_{2,} \omega_{+}>\omega_{-}$ Another interesting point to note is that from Eq. (2.34), $u_{1}$ and $u_{2}$ are periodic with $q= \pm 2 \pi / a$. Therefore, the dispersion relation repeats itelf for each Brillouin zone. From the previous discussions, we obtain the following results.

The vibrational frequency of a diatomic linear chain of mass $M_{1}$ and $M_{2}$ is shown in Figure 2.7.

The first branch, $\omega_{-}$, which tends to become Optical and acoustic phonon branches of a diatomic zero at $q=0$, is known as the acoustic mode.

FIGURE 2.7 linear chain.

optic mode

Figure 8.10 Transverse acoustic and optic modes of motion in a one-dimensional diatomic chain at the same wavelength.

## Phonons

Dispersion relationship is how the energy or frequency of vibrations related to the size scale or wavelengths or what happens to vibrational energy in the crystal, i.e., modulus.

$$
E=2 \hbar \omega_{0}\left|\sin \left(\frac{k a}{2}\right)\right|
$$

Density of states is how the total energy is distributed to different frequencies of vibration. This is related to what happens at different wavenumbers to different wavelength phonons.

$$
D(E)=\frac{1}{V} \cdot \frac{\mathrm{~d} Z_{m}(E)}{\mathrm{d} E} \quad \mathcal{Z}=\sum_{N=0}^{\infty} \exp \left(N(\mu-\varepsilon) / k_{\mathrm{B}} T\right)
$$

N is an integer related to the vibrational state k

## Convert dispersion relation to DOS for a 1D wave in the continuum limit

$q=$ wave number: $q=\frac{2 \pi}{\lambda}, A=$ amplitude, $\omega=$ the frequency, $v_{s}=$ the velocity of sound

$$
\omega=v_{s} q \quad \begin{aligned}
& \text { This is a kind of dispersion relation relating energy or } \\
& \text { frequency to wave vector }
\end{aligned}
$$

Wave equation

$$
u=A e^{i(q x-\omega t)} \quad \text { Density of states doesn't depend on time so use: } \quad u=A e^{i(q x)}
$$

Choose periodic boundary condition

$$
u(x=0)=u(x=L)
$$

Apply boundary conditions to $u=A e^{i(q x)} \quad$ Yields $\quad e^{i q L}=1$
This only occurs if: $\quad q=n \frac{2 \pi}{L} \quad$ Since: $\quad e^{i x}=\cos (x)+i \sin (x)$
n are the modes or the number of waves for a given frequency and the maximum number is how many atoms on a line.

## Convert Dispersion relation to DOS For a 1D wave in the continuum limit

 the number of modes in an interval $d q$ in $q$-space equals:$$
q=n \frac{2 \pi}{L} \quad \mathrm{~d} n=\frac{d q}{\frac{2 \pi}{L}}=\frac{L}{2 \pi} d q
$$

This number is the density of states (DOS) at a frequency $\omega$

$$
\begin{gathered}
g(\omega) d \omega=\frac{L}{2 \pi} d q \text { which we turn into: } g(\omega)=\left(\frac{L}{2 \pi}\right) /\left(\frac{d \omega}{d q}\right) \\
\frac{d \omega}{d q}=v_{s} \quad g(\omega)=\left(\frac{L}{2 \pi}\right) \frac{1}{v_{s}} \quad \begin{array}{l}
\text { For modes in positive and negative " } \mathrm{q}=\text { space" } \\
g(\omega)=2\left(\frac{L}{2 \pi} \frac{1}{v_{s}}\right) \quad g(\omega)=\frac{L}{\pi} \frac{1}{v_{s}} \\
\\
\text { A constant density of states like the Einstein Model }
\end{array}
\end{gathered}
$$

$$
E=2 \hbar \omega_{0}\left|\sin \left(\frac{k a}{2}\right)\right|
$$

$$
D(E)=\frac{1}{V} \cdot \frac{\mathrm{~d} Z_{m}(E)}{\mathrm{d} E}
$$

$$
\mathcal{Z}=\sum_{N=0}^{\infty} \exp \left(N(\mu-\varepsilon) / k_{\mathrm{B}} T\right)
$$

## Debye Model <br> Derivation

https://eng.libretexts.org/Bookshelves/Materials Science/Supplemental Modules (Materials Science)/Electronic Properties/Debye Model For Specific Heat

## Debye Model

$$
\begin{gathered}
U \approx \int_{0}^{\sqrt[3]{N}} \int_{0}^{\sqrt[3]{N}} \int_{0}^{\sqrt[3]{N}} E(n) \bar{N}(E(n)) d n_{x} d n_{y} d n_{z} \\
\langle N\rangle_{B E}=\frac{1}{e^{E / k T}-1} \quad \bar{N}(E)=\frac{3}{e^{E / k T}-1} \quad \begin{array}{l}
\text { One Longitudinal Two } \\
\text { Transverse }
\end{array} \\
U=\int_{0}^{\sqrt[3]{N}} \int_{0}^{\sqrt[3]{N}} \int_{0}^{\sqrt[3]{N}} E(n) \frac{3}{e^{E(n) / k T}-1} d n_{x} d n_{y} d n_{z} \\
\left(n_{x}, n_{y}, n_{z}\right)=(n \sin \theta \cos \phi, n \sin \theta \sin \phi, n \cos \theta) \quad \begin{array}{c}
\text { Convert to Spherical } \\
\text { Coordinates }
\end{array}
\end{gathered}
$$

## Debye Model

$$
\begin{gathered}
U \approx \int_{0}^{\pi / 2} \int_{0}^{\pi / 2} \int_{0}^{R} E(n) \frac{3}{e^{E(n) / k T}-1} n^{2} \sin \theta d n d \theta d \phi \\
N=\frac{1}{8} \frac{4}{3} \pi R^{3} \quad R=\sqrt[3]{\frac{6 N}{\pi}} \\
U=\frac{3 \pi}{2} \int_{0}^{R} \frac{h c_{s} n}{2 L} \frac{n^{2}}{e^{h c_{\mathrm{s}} n / 2 L k T}-1} d n \quad E_{n}^{2}=p_{n}^{2} c_{\mathrm{s}}^{2}=\left(\frac{h c_{\mathrm{s}}}{2 L}\right)^{2}\left(n_{x}^{2}+n_{y}^{2}+n_{z}^{2}\right) \\
T_{\mathrm{D}}^{-3} \propto c_{\text {eff }}^{-3}:=(1 / 3) c_{\text {long }}^{-3}+(2 / 3) c_{\text {trans }}^{-3}
\end{gathered}
$$

## Debye Model

$$
\begin{gathered}
U=\frac{3 \pi}{2} k T\left(\frac{2 L k T}{h c_{\mathrm{s}}}\right)^{3} \int_{0}^{h c_{\mathrm{s}} R / 2 L k T} \frac{x^{3}}{e^{x}-1} d x . \quad x=\frac{h c_{\mathrm{s}} n}{2 L k T} \\
T_{\mathrm{D}} \stackrel{\text { def }}{=} \frac{h c_{\mathrm{s}} R}{2 L k}=\frac{h c_{\mathrm{s}}}{2 L k} \sqrt[3]{\frac{6 N}{\pi}}=\frac{h c_{\mathrm{s}}}{2 k} \sqrt[3]{\frac{6}{\pi} \frac{N}{V}} \\
\frac{U}{N k}=9 T\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \int_{0}^{T_{\mathrm{D}} / T} \frac{x^{3}}{e^{x}-1} d x=3 T D_{3}\left(\frac{T_{\mathrm{D}}}{T}\right) \\
\frac{C_{V}}{N k}=9\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \int_{0}^{T_{\mathrm{D}} / T} \frac{x^{4} e^{x}}{\left(e^{x}-1\right)^{2}} d x
\end{gathered}
$$

## Debye Model

$$
\frac{U}{N k}=9 T\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \int_{0}^{T_{\mathrm{D}} / T} \frac{x^{3}}{e^{x}-1} d x=3 T D_{3}\left(\frac{T_{\mathrm{D}}}{T}\right)
$$

In mathematics, the family of Debye functions is defined by

$$
D_{n}(x)=\frac{n}{x^{n}} \int_{0}^{x} \frac{t^{n}}{e^{t}-1} d t
$$

## Limiting values [edit]

$$
\lim _{x \rightarrow 0} D_{n}(x)=1 .
$$

At high T (Dulong-Petit)

The functions are named in honor of Peter Debye, who came across this function (with $n=3$ ) in 1912 when he analytically computed the heat capacity of what is now called the Debye model.

## Derivative [edit]

The derivative obeys the relation

$$
x D_{n}^{\prime}(x)=n\left(B(x)-D_{n}(x)\right),
$$

So far I can't do this
where $B(x)=x /\left(e^{x}-1\right)$ is the Bernoulli function.

$$
\frac{C_{V}}{N k}=9\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \int_{0}^{T_{\mathrm{D}} / T} \frac{x^{4} e^{x}}{\left(e^{x}-1\right)^{2}} d x
$$

## Debye Model

$$
\begin{gathered}
U=\frac{3 \pi}{2} k T\left(\frac{2 L k T}{h c_{\mathrm{s}}}\right)^{3} \int_{0}^{h c_{\mathrm{s}} R / 2 L k T} \frac{x^{3}}{e^{x}-1} d x . \quad x=\frac{h c_{\mathrm{s}} n}{2 L k T} \\
T_{\mathrm{D}} \stackrel{\text { def }}{=} \frac{h c_{\mathrm{s}} R}{2 L k}=\frac{h c_{\mathrm{s}}}{2 L k} \sqrt[3]{\frac{6 N}{\pi}}=\frac{h c_{\mathrm{s}}}{2 k} \sqrt[3]{\frac{6}{\pi} \frac{N}{V}} \\
\frac{U}{N k}=9 T\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \int_{0}^{T_{\mathrm{D}} / T} \frac{x^{3}}{e^{x}-1} d x=3 T D_{3}\left(\frac{T_{\mathrm{D}}}{T}\right) \\
\frac{C_{V}}{N k}=9\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \int_{0}^{T_{\mathrm{D}} / T} \frac{x^{4} e^{x}}{\left(e^{x}-1\right)^{2}} d x
\end{gathered}
$$

## Debye Model

## Low-temperature limit

The temperature of a Debye solid is said to be low if $T \ll T_{\mathrm{D}}$, leading to

$$
\frac{C_{V}}{N k} \sim 9\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \int_{0}^{\infty} \frac{x^{4} e^{x}}{\left(e^{x}-1\right)^{2}} d x
$$

$$
\mathrm{x}=\mathrm{T}_{\mathrm{D}} / \mathrm{T}
$$

This definite integral can be evaluated exactly:

$$
\frac{C_{V}}{N k} \sim \frac{12 \pi^{4}}{5}\left(\frac{T}{T_{\mathrm{D}}}\right)^{3}
$$

## Debye Model

## High-temperature limit

The temperature of a Debye solid is said to be high if $T \gg T_{\mathrm{D}}$. Using $e^{x}-1 \approx x$ if $|x| \ll 1$ leads to

$$
\frac{C_{V}}{N k} \sim 9\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \int_{0}^{T_{\mathrm{D}} / T} \frac{x^{4}}{x^{2}} d x
$$

where

$$
\frac{C_{V}}{N k} \sim 3
$$

## Debye Model

Debye

$$
\begin{aligned}
& \frac{C_{V}}{N k}=9\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \int_{0}^{T_{\mathrm{D}} / T} \frac{x^{4} e^{x}}{\left(e^{x}-1\right)^{2}} d x \quad C_{V}=3 N k\left(\frac{\epsilon}{k T}\right)^{2} \frac{e^{\epsilon / k T}}{\left(e^{\epsilon / k T}-1\right)^{2}} \\
& T_{\mathrm{D}} \stackrel{\text { def }}{=} \frac{h c_{\mathrm{s}}}{2 k} \sqrt[3]{\frac{6}{\pi} \frac{N}{V}} \\
& \frac{T_{\mathrm{E}}}{T_{\mathrm{D}}}=\sqrt[3]{\frac{\pi}{6}}=0.805995977 \ldots
\end{aligned}
$$

## Debye Model

Debye

$$
\frac{C_{V}}{N k} \sim \frac{12 \pi^{4}}{5}\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \quad \begin{aligned}
& \text { Exponential approach to } \mathrm{T}=0 \\
& C_{V}=3 N k\left(\frac{\epsilon}{k T}\right)^{2} \frac{1}{e^{\epsilon / k T}}
\end{aligned}
$$

Low T $\frac{C_{V}}{N k} \sim \frac{12 \pi^{4}}{5}\left(\frac{T}{T_{\mathrm{D}}}\right)^{3} \quad \begin{aligned} & \text { Exponential approach to T=0} \\ & C_{V}=3 N k\left(\frac{\epsilon}{k T}\right)^{2} \frac{1}{e^{\epsilon / k T}}\end{aligned} \quad \frac{C_{V}}{N k} \sim 3$

High T

$$
\begin{aligned}
\frac{C_{V}}{N k} \sim 3 & \frac{C_{V}}{N k} \sim 3 \\
& \frac{T_{\mathrm{E}}}{T_{\mathrm{D}}}=\sqrt[3]{\frac{\pi}{6}}=0.805995977 \ldots
\end{aligned}
$$

$$
\frac{C_{V}}{N k} \sim 3
$$

## The high temperature limit $k_{B} T \gg \hbar \omega_{D}$

The energy spectral density is,

$$
u(\omega)=\frac{3 \omega^{2}}{2 \pi^{2} c^{3}} \frac{\hbar \omega}{\exp \left(\frac{\hbar \omega}{k_{B} T}\right)-1} .
$$

In the high temperature limit, the exponential factor can be expanded as $\exp \left(\frac{\hbar \omega}{k_{B} T}\right) \approx 1+\frac{\hbar \omega}{k_{B} T}$. The energy spectral density then becomes,

$$
u(\omega)=\frac{3 \omega^{2}}{2 \pi^{2} c^{3}} k_{B} T .
$$

This can be integrated to yield the internal energy density,

$$
u=\frac{\omega_{D}^{3}}{2 \pi^{2} c^{3}} k_{B} T=3 n k_{B} T .
$$

The specific heat has the Dulong-Petit form,

$$
c_{v}=3 n k_{B} .
$$

## Phonon density of states of the Debye model

In the Debye model, the dispersion relation is linear, $\omega=c|k|$, and the density of states is quadratic as it is in the long wavelength limit.

$$
D(\omega)=\frac{3 \omega^{2}}{2 \pi^{2} c^{3}} \quad\left[\mathrm{~s} \mathrm{rad}^{-1} \mathrm{~m}^{-3}\right]
$$

Here $c$ is the speed of sound. This holds up to a maximum frequency called the Debye frequency $\omega_{D}$. In three dimensions there are 3 degrees of freedom per atom so the total number of phonon modes is $3 n$.

$$
3 n=\int_{0}^{\omega D} D(\omega) d \omega
$$

Here $n$ is the atomic density. There are no phonon modes with a frequency above the Debye frequency. The Debye freqency is $\omega_{D}^{3}=6 \pi^{2} n c^{3}$.
The form below generates a table of where the first column is the angular frequency $\omega$ in rad/s and the second column is the density of states $D(\omega)$ in units of $\mathrm{s} /\left(\mathrm{rad} \mathrm{m}^{3}\right)$.

## Debye Model

Figure 8.12 Experimental heat capacity of Cu at constant pressure compared with the Debye and Einstein $C_{V, \mathrm{~m}}$ calculated by using $\Theta_{\mathrm{E}}=244 \mathrm{~K}$ and $\Theta_{\mathrm{D}}=314 \mathrm{~K}$. The vibrational density of states according to the two models is shown in the insert.

At low temperature
Low energy, low frequency vibrations are excited
These are acoustic mode vibrations
Unit cell vibrates as an entity
Long distances compared to a unit cell

Distribution of frequencies, $g(\omega)$, above a cutoff frequency, $\omega_{D}$
$g(\omega)=\frac{3 \omega^{2}}{\omega_{\mathrm{D}}^{3}}$ for $\omega_{\mathrm{D}} \geq \omega$
$g(\omega)=0$ for $\omega>\omega_{\mathrm{D}}$

## Debye Model

Figure 8.12 Experimental heat capacity of Cu at constant pressure compared with the Debye and Einstein $C_{V, \mathrm{~m}}$ calculated by using $\Theta_{\mathrm{E}}=244 \mathrm{~K}$ and $\Theta_{\mathrm{D}}=314 \mathrm{~K}$. The vibrational density of states according to the two models is shown in the insert.

At low temperature
Low energy, low frequency vibrations are excited
These are acoustic mode vibrations
Unit cell vibrates as an entity
Long distances compared to a unit cell

## Quantized energy levels

$\varepsilon=\hbar \omega$
Energy also equals kT
This defines the Debye temperature, $\theta_{n}$
$\Theta_{\mathrm{D}}=\frac{\hbar \omega_{\mathrm{D}}}{k_{\mathrm{B}}}=2 \pi \frac{h v_{\mathrm{D}}}{k_{\mathrm{B}}}$

## Debye Model

$$
\Theta_{\mathrm{D}}=\frac{\hbar \omega_{\mathrm{D}}}{k_{\mathrm{B}}}=2 \pi \frac{h v_{\mathrm{D}}}{k_{\mathrm{B}}}
$$

## Einstein Model

$C_{V, \mathrm{~m}}=\left(\frac{\mathrm{d} \bar{U}}{\mathrm{~d} T}\right)_{V}=3 R\left(\frac{\Theta_{\mathrm{E}}}{T}\right)^{2} \frac{\exp \left(\Theta_{\mathrm{E}} / T\right)}{\left[\exp \left(\Theta_{\mathrm{E}} / T\right)-1\right]^{2}}$
Einstein temperature: $\Theta_{\mathrm{E}}=\frac{\hbar \omega_{\mathrm{E}}}{k_{\mathrm{B}}}$

Heat Capacity is given by,

$$
C_{V, \mathrm{~m}}=9 R\left(\frac{T}{\Theta_{\mathrm{D}}}\right)^{3} \int_{0}^{\Theta_{\mathrm{D}} / T} \frac{e^{x}}{\left(e^{x}-1\right)^{2}} x^{4} \mathrm{~d} x
$$

At Low T this reduces to, $\quad C_{V}=\frac{12 \pi^{4}}{5} R\left(\frac{T}{\Theta_{\mathrm{D}}}\right)^{3}$

The $\mathrm{T}^{3}$ dependence is seen experimentally

Figure 8.12 Experimental heat capacity of Cu at constant pressure compared with the Debye and Einstein $C_{V, \mathrm{~m}}$ calculated by using $\Theta_{\mathrm{E}}=244 \mathrm{~K}$ and $\Theta_{\mathrm{D}}=314 \mathrm{~K}$. The vibrational density of states according to the two models is shown in the insert.

Higher Characteristic T represents stronger bonds

Higher Characteristic T represents stronger bonds

Figure 8.13 Lattice heat capacity of three different polymorphs of carbon; $\mathrm{C}_{60}$ [5], graphite and diamond.

Table 8.2. Debye temperature $\left(\Theta_{\mathrm{D}}\right.$ in K$)$ and electronic heat capacity coefficient (see Section 8.4) $\left(\gamma \mathrm{in} \mathrm{mJ} \mathrm{K}^{-1} \mathrm{~mol}^{-1}\right)$ of the elements.

Figure 8.14 Debye temperature of the alkali halides.

## Modulus and Heat Capacity

$$
\begin{aligned}
& \sigma=E \varepsilon \\
& F / A=E \Delta d / d \\
& F=K \Delta d \\
& K=F / \Delta d=E A / d
\end{aligned}
$$

At large $\mathrm{q}, \omega=\sqrt{ }(4 \mathrm{~K} / \mathrm{m})$
This yields $\omega_{D}$ from E

For $\mathrm{Cu}, \theta_{\mathrm{D}}=344 \mathrm{~K}$

$$
\begin{gathered}
\Theta_{\mathrm{D}}=\frac{\hbar \omega_{\mathrm{D}}}{k_{\mathrm{B}}}=2 \pi \frac{h v_{\mathrm{D}}}{k_{\mathrm{B}}} \\
\omega_{\mathrm{D}}=32 \mathrm{THz} \\
\mathrm{~K}=13.4 \mathrm{~N} / \mathrm{m} \\
\omega_{\mathrm{D}}=18 \mathrm{THz}
\end{gathered}
$$

## Modulus and Heat Capacity

The Debye Temperature reflects the highest energy, lowest wave vector vibrations so the linear part of the dispersion curve

$$

## How to obtain $\mathrm{C}_{\mathrm{p}}$ from calculated $\mathrm{C}_{\mathrm{V}}$ ?

$$
C_{p, \mathrm{~m}}-C_{V, \mathrm{~m}}=\frac{\alpha^{2} V T}{\kappa_{T}}
$$

At low T

$$
C_{V}=C_{p}
$$

The harmonic oscillator model assumes constant volume So deviations for constant pressure are related to "anharmonic" vibrations
Anharmonic vibrations contribute to the heat capacity They also lead to a finite thermal expansion coefficient

Figure 8.12 Experimental heat capacity of Cu at constant pressure compared with the Debye and Einstein $C_{V, \mathrm{~m}}$ calculated by using $\Theta_{\mathrm{E}}=244 \mathrm{~K}$ and $\Theta_{\mathrm{D}}=314 \mathrm{~K}$. The vibrational density of states according to the two models is shown in the insert.

Anharmonic vs Harmonic Contributions to Heat Capacity (due to thermal expansion and thermal conductivity)

Figure $8.15 C_{p, \mathrm{~m}}-C_{V, \mathrm{~m}}$ and $C_{V, \mathrm{~m}}-C_{V, \mathrm{~m}, \mathrm{fix}}$ for Mo and W [6

## Approximate relationships for $\mathbf{C}_{\mathbf{p}}-\mathbf{C}_{\mathbf{V}}$

Nernst-Lindeman relationship If you don't know the thermal expansion coefficient

$$
C_{p, \mathrm{~m}}-C_{V, \mathrm{~m}}=\frac{V \alpha^{2}}{\kappa_{T} C_{p, \mathrm{~m}}^{2}} C_{p, \mathrm{~m}}^{2} T=A C_{p, \mathrm{~m}}^{2} T \quad C_{p, \mathrm{~m}}-C_{V, \mathrm{~m}}=\frac{\alpha^{2} V T}{\kappa_{T}}
$$

If you know the thermal expansion coefficient,

$$
\begin{array}{lr}
C_{p, \mathrm{~m}}-C_{V, \mathrm{~m}}=\gamma_{\mathrm{G}} \alpha C_{V, \mathrm{~m}} T & C_{p, \mathrm{~m}}-C_{V, \mathrm{~m}}=\frac{\alpha^{2} V T}{\kappa_{T}} \\
\gamma_{\mathrm{G}}=\left[\frac{\partial p}{\partial(U / V)}\right]_{V}=\frac{\alpha V}{\kappa_{T} C_{V, \mathrm{~m}}} & \text { Grüneisen parameter }
\end{array}
$$

## Density of states $\rightarrow$ Specific heat

The specific heat is the derivative of the internal energy with respect to the temperature.

$$
c_{v}=\left(\frac{\partial u}{\partial T}\right)_{V, N}
$$

This can be expressed in terms of an integral over the frequency $\omega$.

$$
c_{v}=\frac{\partial}{\partial T} \int u(\omega) d \omega=\frac{\partial}{\partial T} \int \hbar \omega D(\omega) \frac{1}{e^{\frac{\hbar \omega}{k_{B} T}}-1} d \omega
$$

The Leibniz integral rule can be used to bring the differentiation inside the integral. If the photon density of states $D(\omega)$ is temperature independent, the result is,

$$
c_{v}=\int \hbar \omega D(\omega) \frac{\partial}{\partial T}\left(\frac{1}{e^{\frac{\hbar \omega}{k_{B} T}}-1}\right) d \omega
$$

Since only the Bose-Einstein factor depends on temperature, the differentiation can be performed analytically and the expression for the specific heat is,

$$
c_{v}=\int\left(\frac{\hbar \omega}{T}\right)^{2} \frac{D(\omega) e^{\frac{\hbar \omega}{k_{B} T}}}{k_{B} \cdot\left(e^{\frac{\hbar \omega}{k_{B} T}}-1\right)^{2}} d \omega
$$

100th Anniversary of Brillouin Scattering: Impact on Materials Science

Seif Kofima Materials 2022, 15, 3518.

Figure 3. Broadband inelastic light scattering spectrum of a ferroelectric $\mathrm{Pb}\left(\mathrm{Sc}_{1 / 2} \mathrm{Ta}_{1 / 2}\right) \mathrm{O}_{3}$ crystal. Brillouin and Raman scattering spectra were measured by a tandem multi-pass FPI and triple-grating spectrometer, respectively [22].

## Entropy from Heat Capacity

-SUV
H A
-pGT
$\mathrm{C}_{\mathrm{V}}=(\mathrm{dU} / \mathrm{dT})_{\mathrm{V}}$
From the Thermodynamic Square
$\mathrm{dU}=\mathrm{TdS}-\mathrm{pdV}$ so $\mathrm{C}_{\mathrm{V}}=(\mathrm{dU} / \mathrm{dT})_{\mathrm{V}}=\mathrm{T}(\mathrm{dS} / \mathrm{dT})_{\mathrm{V}}-\mathrm{p}(\mathrm{dV} / \mathrm{dT})_{\mathrm{V}}$
Second term is 0 dV at constant V is 0
$(\mathrm{dS} / \mathrm{dT})_{\mathrm{V}}=\mathrm{C}_{\mathrm{V}} / \mathrm{T}$
Similarly
$C_{p}=(d H / d T)_{p}$
From the Thermodynamic Square
$\mathrm{dH}=\mathrm{TdS}+\mathrm{Vdp}$ so $\mathrm{C}_{\mathrm{p}}=(\mathrm{dH} / \mathrm{dT})_{\mathrm{p}}=\mathrm{T}(\mathrm{dS} / \mathrm{dT})_{\mathrm{p}}-\mathrm{V}(\mathrm{dp} / \mathrm{dT})_{\mathrm{p}}$
Second term is 0 dp at constant p is 0
$(d S / d T)_{p}=C_{p} / T$
Integrate $\mathrm{C}_{\mathrm{p}} / \mathrm{T} d T$ or Integrate $\mathrm{C}_{\mathrm{V}} / \mathrm{T} \mathrm{dT}$ to obtain S

## Low Temperatures Solve Numerically High Temperatures Series Expansion

$$
S=3 R\left[\frac{4}{3}+\ln \left(\frac{T}{\theta_{i}}\right)+\frac{1}{40}\left(\frac{\theta_{i}}{T}\right)^{2}-\frac{1}{2240}\left(\frac{\theta_{i}}{T}\right)^{4}+\ldots\right]
$$

$$

$\Delta \mathrm{S}$ and $\Delta \mathrm{V}$ have the same sign

This isn't true with a change in oxidation state or coordination number
Tetrahedral Si Octahedral Si 50\% Octahedral Si
pyroxene $>$ perovskite $>$ garnet $>$ ilmenite entropy
Tetrahedral Si 50\% Octahedral Si Octahedral Si pyroxene < garnet < ilmenite < perovskite Density = mass/volume

All the Si atoms are tetrahedrally coordinated in pyroxene, while $50 \%$ are tetrahedrally coordinated and $50 \%$ octahedrally coordinated in garnet. In the ilmenite and perovskite modifications all Si atoms are octahedrally coordinated.

## Electronic Heat Capacity

Electrons that escape from the valence band to the conduction band have three degrees of freedom so contribute $3 / 2 \mathrm{R}$ to the heat capacity (Drude Model of conduction)
For monovalent Cu we expect Dulong Petit 3 R plus $3 / 2 \mathrm{R}$ (but we see only 3 R so where is the $3 / 2 \mathrm{R}$ ?)

For $\mathrm{Cu},(3+3 / 2) \mathrm{R}$ this isn't seen due to quantization of the electron energy level

Fermi Level = Electron energy level that at equilibrium is $50 \%$ occupied

Electrons above this energy are free electrons on average

Figure 8.19 Energy distribution for a free electron gas at 0 K (shaded) and an elevated tem-

Figure 8.20 Heat capacity of a free electron gas. The population of the electronic states at different temperatures is shown in the insert. $T_{\mathrm{F}}$ is typically of the order of $10^{5} \mathrm{~K}$.

$$
\Delta U=N_{1} k_{\mathrm{B}} T
$$

$\mathrm{N}_{1}$ is the number of electrons excited by kT
These occupy electronic states in a band of kT about the Fermi level

$$
N_{1}=n\left(\varepsilon_{\mathrm{F}}\right) k_{\mathrm{B}} T \quad \begin{aligned}
& \mathrm{n}\left(\varepsilon_{\mathrm{F}}\right) \text { is the number of } \\
& \text { electrons at the Fermi level }
\end{aligned}
$$

$$
\Delta U=n\left(\varepsilon_{\mathrm{F}}\right) k_{B}^{2} T^{2}
$$

$$
C_{\mathrm{E}}=\frac{\partial \Delta U}{\partial T}=2 n\left(\varepsilon_{\mathrm{F}}\right) k_{\mathrm{B}}^{2} T
$$

$$
C_{\mathrm{E}}=\gamma T
$$

$\gamma$ is the electronic heat capacity coefficient
$\gamma$ is 0 for an insulator and has a value for a metal

Table 8.2. Debye temperature $\left(\Theta_{D}\right.$ in K$)$ and electronic heat capacity coefficient (see Section 8.4) $\left(\gamma \mathrm{in} \mathrm{mJ} \mathrm{K}^{-1} \mathrm{~mol}^{-1}\right)$ of the elements.

## For $\mathrm{T}<10 \mathrm{~K}$

$$
C_{V}=\beta T^{3}+\gamma T
$$

Figure 8.21 Heat capacity of Cu plotted as $C_{p, \mathrm{~m}} \cdot T^{-1}$ versus $T^{2}$.

$C_{\mathrm{E}}=\frac{\partial \Delta U}{\partial T}=2 n\left(\varepsilon_{\mathrm{F}}\right) k_{\mathrm{B}}^{2} T$
$C_{\mathrm{E}}=\gamma T$

Figure 8.22 Variation of the electronic heat capacity coefficient with composition for the alloys $\mathrm{Rh}-\mathrm{Pd}$ and $\mathrm{Pd}-\mathrm{Ag}$ [17]. Solid and dotted lines represent the electronic DoS for the 5 s and 4 d bands, respectively.

A striking example is the electronic heat capacity coefficients observed for $\mathrm{Rh}-\mathrm{Pd}-\mathrm{Ag}$ alloys given in Figure 8.22 [17]. In the rigid band approach, the addition of Ag to Pd gives an extra electron per atom of silver and these electrons fill the band to a higher energy level. Correspondingly, alloying with Rh gives an electron hole per Rh atom and the Fermi level is moved to a lower energy. The variation of the electronic heat capacity coefficient with composition of the alloy maps approximately the shape of such an electron band.

Slide 93 for density of states

## Magnetic Heat Capacity

Magnetic excitation
$c_{v}=\int\left(\frac{\hbar \omega}{T}\right)^{2} \frac{D(\omega) e^{\frac{\hbar \omega}{k_{B} T}}}{k_{B} \cdot\left(e^{\frac{\hbar}{k_{B} T}}-1\right)^{2}} d \omega$

Magnon
Spin waves

$$
C_{\text {magn }}=R \int \frac{x^{2} \mathrm{e}^{x}}{\left(e^{x}-1\right)^{2}} g_{\text {magn }}
$$

$$
(\omega) \mathrm{d} \omega
$$

$$
x=\hbar \omega / k_{\mathrm{B}} T
$$

Ferromagnet $\mathrm{T}^{3 / 2}$ at low T

Spin waves are propagating disturbances in the ordering of magnetic materials.

## Heat Capacity for Systems that Display a Transition

Rate of entropy change with $\mathrm{T}, \mathrm{C}_{\mathrm{v}}=\mathrm{T}(\mathrm{dS} / \mathrm{dT})_{\mathrm{V}}$,
-increases as kT approaches the transition temperature.
-At high temperatures all states are active so the change in entropy is small.

This results in a peak in $\mathrm{C}_{\mathrm{v}}$ and $\mathrm{C}_{\mathrm{p}}$

## From Kittel and Kroemer Thermal Physics Chapter 2

For a system with quantized energy and two states $\varepsilon_{1}$ and $\varepsilon_{2}$, the ratio of the probabilities of the two states is given by the Boltzmann potentials, ( $\tau$ is the temperature $\mathrm{k}_{\mathrm{B}} \mathrm{T}$ )

$$
\frac{P\left(\varepsilon_{1}\right)}{P\left(\varepsilon_{2}\right)}=\frac{\exp \left(-\varepsilon_{1} / \tau\right)}{\exp \left(-\varepsilon_{2} / \tau\right)} .
$$

If state $\varepsilon_{2}$ is the ground state, $\varepsilon_{2}=0$, and the sum of exponentials is called the partition function $Z$, and the sum of probabilities equals 1 then,
$Z=\exp \left(-\varepsilon_{2} / \tau\right)+1 \quad U \equiv\langle\varepsilon\rangle=\frac{\varepsilon \exp \left(-\varepsilon_{i} \tau\right)}{Z}=\varepsilon \frac{\exp (-\varepsilon / \tau)}{1+\exp (-\varepsilon / \tau)} . \quad C_{V}=(\partial U / \partial \tau)_{V}$,
Z normalizes the probability for a state "s"
$P\left(\varepsilon_{s}\right)=\exp \left(-\varepsilon_{s} / \tau\right) / Z$

$$
C_{V}=k_{B}\left(\frac{\varepsilon}{k_{B} T}\right)^{2} \frac{\exp \left(\varepsilon / k_{B} T\right)}{\left[\exp \left(\varepsilon / k_{\mathrm{L}} T\right)+1\right]^{2}} .
$$

The average energy for the system is $U=\left(\sum \varepsilon_{i} e^{-\varepsilon_{i} / \tau}\right) /{ }_{Z}=\tau^{2}\left(\frac{d \ln Z}{d \tau}\right)$

From Kittel and Kroemer Thermal Physics Chapter 2

$$
\begin{gathered}
U \equiv\langle\varepsilon\rangle=\frac{\varepsilon \exp \left(-\varepsilon_{i} \tau\right)}{Z}=\varepsilon \frac{\exp (-\varepsilon / \tau)}{1+\exp (-\varepsilon / \tau)} . \\
C_{V}=k_{B}\left(\frac{\varepsilon}{k_{B} T}\right)^{2} \frac{\exp \left(\varepsilon / k_{B} T\right)}{\left[\exp \left(\varepsilon / k_{11} T\right)+1\right]^{2}} .
\end{gathered}
$$

$$
\begin{array}{ll}
\text { First term } & \text { Second term } \\
\text { decays with } & \text { increases with } \\
(\varepsilon / \mathrm{kT})^{2} & \sim \exp (-\varepsilon / \mathrm{kT})
\end{array}
$$

## Metal-Insulator Transition

First order transition at $\mathrm{T}_{\text {trs }}$ between an insulator $\gamma=0$ and a metal $\gamma=\gamma$ met

A quantum transition, critical quantum behavior

$$
\Delta_{\text {ins-met }} S_{\mathrm{m}}=\gamma_{\mathrm{met}} T_{\mathrm{trs}}
$$

Transition can occur on doping of an oxide like $\mathrm{Fe}_{2} \mathrm{O}_{3}$
Temperature or Pressure Changes

$$
(\mathrm{dS} / \mathrm{dT})_{\mathrm{p}}=\mathrm{C}_{\mathrm{p}} / \mathrm{T}
$$

## Magnetic Order-Disorder Transition

At the Curie temperature material goes from a ferromagnet to a paramagnet and loses magnetic order This impacts the entropy and heat capacity

Maximum total order-disorder entropy can be calculated, $\Delta \mathrm{S}$ $N_{\text {un }}$ unpaired electrons total spin quantum number $\mathscr{S}=\Sigma \frac{1}{2} N_{\text {un }}$ $(2 \mathscr{S}+1)$ quantized orientations

$$
k_{\mathrm{B}} \ln (2 \mathscr{S}+1) \text { per particle }
$$

$$
\Delta S=R \ln (2 \mathscr{S}+1)
$$

Figure 8.23 Heat capacity of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ [18]. The heat capacity is deconvoluted to show the relative magnitude of the main contributions. $C_{\mathrm{dil}}=C_{p, \mathrm{~m}}-C_{V, \mathrm{~m}}=\alpha^{2} T V / \kappa_{\mathrm{T}}$.
$(\mathrm{dS} / \mathrm{dT})_{\mathrm{p}}=\mathrm{C}_{\mathrm{p}} / \mathrm{T}$

## $\mathrm{CO}_{3} \mathrm{O}_{4}$ Transitions

Cathode in $\mathrm{Li}^{+}$batteries or blue pigment for pottery

The spinel structure is formulated $\mathrm{MM}^{\prime}{ }_{2} \mathrm{X}_{4}$, where M and $\mathrm{M}^{\prime}$ are tetrahedrally and octahedrally coordinated cations, respectively, and X is an anion (typically O or F ). The structure is named after the mineral $\mathrm{MgAl}_{2} \mathrm{O}_{4}$, and oxide spinels have the general formula $\mathrm{AB}_{2} \mathrm{O}_{4}$.

## $\mathrm{Co}_{3} \mathrm{O}_{4}$ Transitions

The normal spinel contains Co2+ at tetrahedral sites and lowspin Co3+ at octahedral sites. The heat capacity effect observed at $T \beta 900 \mathrm{~K}$ is in part a low- to high-spin transition of the Co3+ ions and in part a partial transition from normal toward random distribution of $\mathrm{Co3+}$ and $\mathrm{Co} 2+$ on the tetrahedral and octahedral sites of the spinel structure. The insert to the figure shows the magnetic order-disorder transition of $\mathrm{Co}_{3} \mathrm{O}_{4}$ at around 30 K .

Figure 8.24 Heat capacity of $\mathrm{Co}_{3} \mathrm{O}_{4}$ [23-25]. The insert shows the magnetic order-disorder transition at around 30 K [24] in detail.

| Schottky Defect | Frenkel Defect |
| :--- | :--- |
| Schottky defect occurs in those ionic crystals <br> where difference in size between cation and anion <br> is small. | Frenkel defect usually occurs in those ionic <br> crystals where size of anion is quite large as <br> compared to that of the cation. |
| In Schottky defect, both cation and anion leave the <br> solid crystal. | In Frenkel defect, only the smaller ion (cation) <br> leaves its original lattice site; whereas, the anion <br> remains in original lattice sites. |
| The atoms permanently leave the crystal. | Here, atoms leave the original lattice site and <br> occupy interstitial position. So atoms reside within <br> the solid crystal. |
| One Schottky defect leads to the formation of two <br> vacancies. | One Frenkel defect creates one vacancy and one <br> self-interstitial defect. |
| Two atoms reduce from the crystal for each <br> Schottky defect. | The number of atoms present in the crystal before <br> and after Frenkel defect remains same. |
| Due to vacancy formation, Schottky defect reduces <br> density of the solid. | Density of the solid crystal before and after Frenkel <br> defect remains same as no atom leaves the solid. |
| Common materials where Schottky defect can be <br> found are: | Common materials where Frenkel defect can be <br> found are: |
| - Sodium Chloride (NaCl) |  |
| - Potassium Chloride (KCl) |  |
| - Potassium Bromide (KBr) |  |
| - Silver Bromide (AgBr) |  |
| - Cerium Dioxide (CeO $)$ |  |
| - Thorium Dioxide (ThO 2 ) |  |

Two levels with energy spacing $\varepsilon / \mathrm{k}_{\mathrm{B}}$ $T>\varepsilon / k_{B}$ both levels occupied equally $\mathrm{T}<\varepsilon / \mathrm{k}_{\mathrm{B}}$ only lower level occupied Boltzmann statistics yields
$C_{\text {sch }}=R\left(\frac{\varepsilon}{k_{\mathrm{B}} T}\right)^{2}\left(\frac{g_{0}}{g_{1}}\right)\left[\frac{\exp \left(\varepsilon / k_{\mathrm{B}} T\right)}{\left\{1+\left(g_{0} / g_{1}\right) \exp \left(\varepsilon / k_{\mathrm{B}} T\right)\right\}^{2}}\right]$
$g_{0}$ and $g_{1}$ are the degeneracies of the ground level and the excited level

Figure 8.25 The Schottky-type heat capacity of $\mathrm{Nd}_{2} \mathrm{~S}_{3}$ [28]. The insert shows the total heat capacity of $\mathrm{ErFeO}_{3}$ [29].

Endothermic formation enthalpy
Entropy associated with disorder of defect location

$$
\begin{gathered}
C_{V, \mathrm{~m}}=\frac{1}{R T^{2}}\left[\Delta_{\mathrm{vac}} H_{\mathrm{m}}^{2} \exp \left(\frac{\Delta_{\mathrm{vac}} S_{\mathrm{m}}}{R}\right)\right] \exp \left(-\frac{\Delta_{\mathrm{vac}} H_{\mathrm{m}}}{R T}\right) \\
C_{\mathrm{sch}}=R\left(\frac{\varepsilon}{k_{\mathrm{B}} T}\right)^{2}\left(\frac{g_{0}}{g_{1}}\right)\left[\frac{\exp \left(\varepsilon / k_{\mathrm{B}} T\right)}{\left\{1+\left(g_{0} / g_{1}\right) \exp \left(\varepsilon / k_{\mathrm{B}} T\right)\right\}^{2}}\right] \quad \Delta \mathrm{G}=\Delta \mathrm{H}-\mathrm{T} \Delta \mathrm{~S} \\
(\mathrm{dS} / \mathrm{dT})_{\mathrm{V}}=\mathrm{C}_{\mathrm{V}} / \mathrm{T}
\end{gathered}
$$

## Fast Ion Conductors (solid oxide fuel cells high T)

Solid electrolytes for batteries and fuel cells

AgI , I lattice remains intact, $\mathrm{Ag}+$ conductor becomes a liquid
Also, $\mathrm{Cu}_{2} \mathrm{~S}, \mathrm{Ag}_{2} \mathrm{~S}$. NaS battery

Heat Capacity drops with temperature

$$
C_{V}=k_{B}\left(\frac{\varepsilon}{k_{B} T}\right)^{2} \frac{\exp \left(\varepsilon / k_{B} T\right)}{\left[\exp \left(\varepsilon / k_{\mathrm{H}} T\right)+1\right]^{2}} .
$$

First term decays with $(\varepsilon / \mathrm{kT})^{2}$

Second term
increases with $\sim \exp (-\varepsilon / k T)$

Liquids and Glasses

$$
\mathrm{C}_{\mathrm{p}}=(\mathrm{dH} / \mathrm{dT})_{\mathrm{P}}=(\mathrm{dQ} / \mathrm{dT})_{\mathrm{P}}=((\mathrm{dQ} / \mathrm{dt})(\mathrm{dT} / \mathrm{dt}))_{\mathrm{P}} \quad \text { A. amorphous }
$$

(:)

Temperature

## Liquids and Glasses

Figure 5.1 (a) Heat capacity of crystalline, liquid and supercooled liquid Se as a function of temperature [1-3]. (b) Entropy of crystalline, liquid and supercooled liquid Se as a function of temperature.

Broad minimum in heat capacity

Loss of short-range order with rising T leads to drop in heat capacity

Initially, loss of vibrational degrees of freedom associated with short range order lead to decrease in $C_{p}$

Later, S increases with T

$$
\mathrm{T}(\mathrm{dS} / \mathrm{dT})_{\mathrm{p}}=\mathrm{C}_{\mathrm{p}}
$$

## Anomalous behavior of glasses near absolute 0

Debye $\mathrm{C}_{\mathrm{V}} \sim \mathrm{T}^{3}$ near 0 K

Behavior is due to anharmonic vibrations (Relaxation phenomena)

Figure 8.26 Heat capacity of glassy and crystalline $\mathrm{B}_{2} \mathrm{O}_{3}$ [42-44] and glassy Se [41] plotted as $C_{p, \mathrm{~m}} \cdot T^{-3}$ versus $T$.

## Pseudo-second order transition behavior of glasses

Relaxation phenomena In glasses

Figure 8.27 Heat capacity of some glass-forming liquids close to their glass transition temperatures: $\mathrm{ZnCl}_{2}$ [45], $\mathrm{GeSe}_{2}$ [46], and a selected titanosilicate [47], aluminosilicate [48] and borosilicate [49] system.

## Pseudo-second order transition behavior of glasses

Figure 8.28 Heat capacity of glassy $\mathrm{B}_{2} \mathrm{O}_{3}$ at different heating rates [50].

## Pseudo-second order transition behavior of glasses

Relaxation phenomena In glasses

Figure 8.29 Entropy of a supercooled liquid and glasses formed by fast and slow cooling of this liquid (the different dashed lines). The short dashed line represents slow heating of a glass first prepared by fast cooling.

## Thermodynamic and Kinetic Fragility

Fragile versus strong glass

Kinetics: Deviation from Arrhenius behavior
$\eta=\eta_{0} \exp \left(-E_{a} / k_{B} T\right)$
Scaled Exponential
$\eta=\eta_{0} \exp \left(-E_{a} / k_{B} T\right)^{m}$

$$
m:=\left(\frac{\partial \log _{10} \eta}{\partial\left(T_{g} / T\right)}\right)_{T=T g}=\frac{1}{\ln 10}\left(\frac{\partial \ln \eta}{\partial\left(T_{g} / T\right)}\right)_{T=T g}=\frac{T_{g}}{\ln 10}\left(\frac{-\partial \ln \eta}{\partial T}\right)_{T=T g}
$$

## Heat Capacity of Polymers

Amorphous structure but with regular order along the chain 1-d vibrational structure

Einstein method works well above 100 K

$$
\begin{gathered}
\mathrm{E}(\theta / T)=\left[(\theta / T)^{2} \exp (\theta / T)\right] /[\exp (\theta / T)-1]^{2} \\
C_{E}=N k \sum_{N_{E}} \mathrm{E}(\theta / T) \\
\mathrm{N}_{\mathrm{E}}=3 N_{\text {Atoms }}-N
\end{gathered}
$$

E is the heat capacity contribution for each vibration
$\begin{aligned} \mathrm{N}_{\text {atoms }}= & \text { number of atoms in a mer unit } \\ & 3 \text { for } \mathrm{CH}_{2}\end{aligned}$
$\mathrm{N}=$ number of skeletal modes of vibration $\mathrm{N}=2$ for $-\left(\mathrm{CH}_{2}\right)_{\mathrm{n}}$ -
$C_{V, \mathrm{~m}}=\left(\frac{\mathrm{d} \bar{U}}{\mathrm{~d} T}\right)_{V}=3 R\left(\frac{\Theta_{\mathrm{E}}}{T}\right)^{2} \frac{\exp \left(\Theta_{\mathrm{E}} / T\right)}{\left[\exp \left(\Theta_{\mathrm{E}} / T\right)-1\right]^{2}}$
Einstein temperature: $\quad \Theta_{\mathrm{E}}=\frac{\hbar \omega_{\mathrm{E}}}{k_{\mathrm{B}}}$

## Below 50K need more detailed breakup of $1 d$ and 3d vibrations using Debye Approach

Weak Van der Waals interactions between chains described by 3d Debye function

$$
\begin{gathered}
\mathbf{D}_{3}\left(\theta / T_{3}\right)=3\left(\theta / T_{3}\right)^{3} \int_{0}^{\theta / T_{3}}\left\{\left[(\theta / T)^{4} \exp (\theta / T)\right] /[\exp (\theta / T)-1]^{2}\right\} \mathrm{d}(\theta / T) \\
C_{v} / 3 N k=\mathrm{D}_{3}\left(\theta / T_{3}\right) \\
\theta_{3}=\mathrm{h} v_{3} / \mathrm{k} \quad \text { For skeletal modes normal to the chain }
\end{gathered}
$$

Strong covalent interactions along chains described by 1d Debye function

$$
\begin{aligned}
& \mathbf{D}_{1}\left(\theta / T_{1}\right)=\left(\theta / T_{1}\right) \int_{0}{ }^{\theta / T_{1}}\left\{\left[(\theta / T)^{2} \exp (\theta / T)\right] /[\exp (\theta / T)-1]^{2}\right\} d(\theta / T) \\
& C_{v} / 3 N k=\mathrm{D}_{1}\left(\theta / T_{1}\right) \\
& \theta / T=\mathrm{h} v_{1} / \mathrm{k} \quad \text { For skeletal vibrations in the chain axis }
\end{aligned}
$$

Linear heat capacity increase from 0 to 200 K
$C_{\vee}$ (Tarasov) $=N R / 3\left\{\mathrm{D}_{1}\left(\theta_{1} / T\right)-\left(\theta_{3} / \theta_{1}\right)\left[\mathrm{D}_{1}\left(\theta_{3} / T\right)-\mathrm{D}_{3}\left(\theta_{3} / T\right)\right]\right\}$

At low frequency 3d vibrations, at high frequency 1 d vibrations

1d Tasarov simplification (generates about $1 \%$ error versus experimental)

$$
C_{T}=N k / 3\left[\left(6.7 T / \theta_{1}\right)^{2} /\left(1+\left(6.7 T / \theta_{1}\right)^{2}\right)\right]
$$

Polystyrene

$N_{\text {atoms }}=16$ atoms per unit
$\mathrm{N}=6$ skeletal mode vibrations 42 total atomic group modes of vibration
$\mathrm{N}_{\mathrm{E}}=3 N_{\text {Atoms }}-N$
$\mathrm{N}_{\mathrm{E}}=42$
$\theta_{1}=285 \mathrm{~K}$

| $\theta$ | Number | $\theta$ | $\frac{\theta}{7}$ |
| :--- | :--- | :--- | :--- |
| 4000 | 8 | 700 | $\frac{\text { Number }}{2}$ |
| 2000 | 10 | 500 | 1 |
| 1500 | 12 | 350 | 1 |
| 1000 | 8 | - | - |

$E(\theta / T)=\left[(\theta / T)^{2} \exp (\theta / T)\right] /[\exp (\theta / T)-1]^{2}$

$$
C_{E}=N k \sum_{N_{E}} \mathrm{E}(\theta / T)
$$

Or calculate with the Tasarov Equatio $C_{T}=6 \mathrm{R}\left[(T / 42.5)^{2} /\left(1+(T / 42.5)^{2}\right)\right]$
